CV

Designing a Notif Service

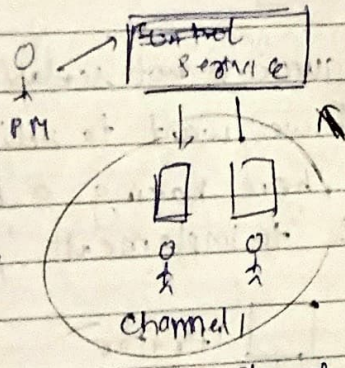
→ sending via all notification channels.

→ templates - all templates in a templat database

channels

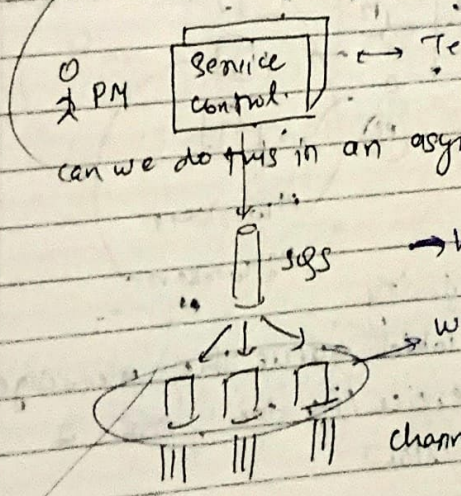
- mail, push notifications, message sms

* each thing like mail/msg has a separate apis/sdk provider which we can use. Using this → all this msgs can be configured in the service being used to send



Bottlenecks shooting load directly to consumer through channels can be really slow.

so we need to do this asynchronously.



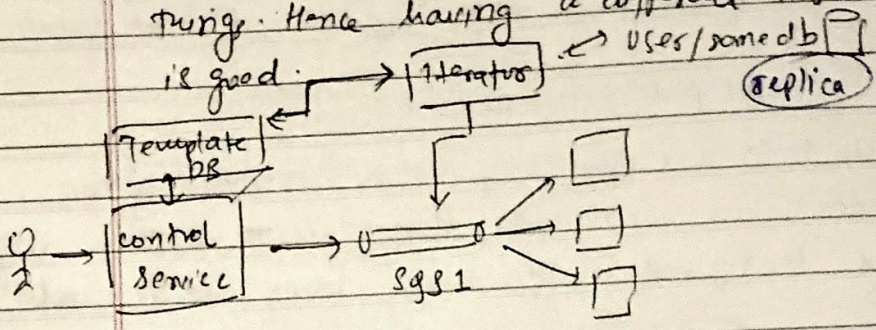
can we do this in an async way?

→ how do retries work here?

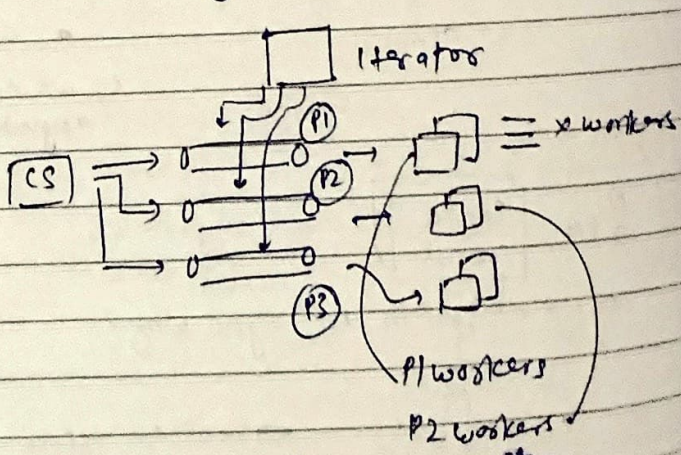
- this works for the case, in which we have a list of users on which we want to send data.

→ If we don't have the list for which we wanna iterate upon, and we wish to fanout the notifications to all, or we want to selectively send the notifications to users with a certain criteria → we might find it difficult to do so using CONTROL SERVICE

because it already takes care of analytics & lots of tuning. Hence having a different Iterate service is good.



The issue here is the queue ~~is not scalable - why~~? will have an issue if we want to deliver something on priority, here having a single queue - it's ~~too~~ tough to implement priority.

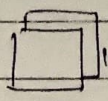


Now the queues have priority.
so depending upon which queue the message is put into by control service / iterator, it will go into that fast/slow

Now, on final caveat, suppose while sending the message to all users, the iterator goes down, we don't want to send the same message again to a users who have previously received the message. so what to do?

Tam Dao & Dunhill

marketing campaign



for a marketing campaign, we can choose or not choose to send notification to that user,

→ this will have all keys from all users, under certain marketing campaign.

Can we do BETTER?

→ we can have bloom filters which will be space efficient with some percentage of incorrectness.
